

Medical Billing and Claims Management System

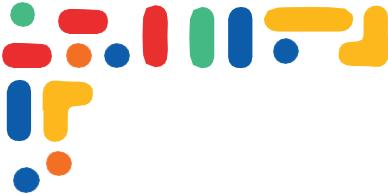

Problem Statement: The Medical Billing and Claims Management System is a comprehensive application designed to streamline the complex process of medical billing, claims submission, and reimbursement for healthcare providers, insurance companies, and patients. The system aims to reduce administrative burdens, improve accuracy, and enhance communication between stakeholders.

Scope:

- Efficient Claims Submission:** Develop a system for healthcare providers to submit accurate and timely insurance claims.
- Claims Processing:** Enable insurance companies to process claims, validate coverage, and reimburse healthcare providers.
- Patient Invoicing:** Generate and manage invoices for patients based on their medical services and insurance coverage.

Use Cases:

Actor - Patient:

- Use Case: Register as a new patient.
- Use Case: Log in as an existing patient.
- Use Case: Update personal information.
- Use Case: view all insurance plan details.
- Use Case: Select an insurance plan.
- Use Case: View invoice.
- Use Case: Submit a claim.

Actor - Healthcare Provider:

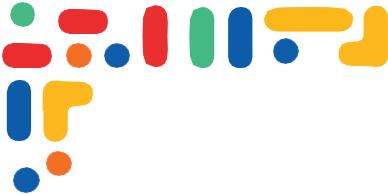

- Use Case: Log in as a healthcare provider.
- Use Case: Generate an invoice.
- Use Case: Notify patient of the invoice.

Actor - Insurance Company:

- Use Case: Review and process claims.
- Use Case: Approve claims.
- Use Case: Process claim payment.
- Use Case: View patient claim history.

Actor - Administrator:

- Use Case: Log in as an administrator.
- Use Case: View system dashboard(claims, payments)
- Use Case: Manage user accounts.

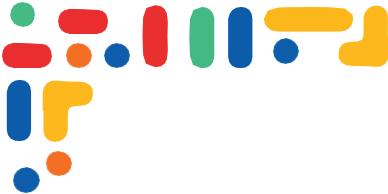

Development Process:

1. Patient Enrollment and Insurance Management

1. The patient accesses the application, registers, and creates a profile.
 - Personal Information:
 - Full Name
 - Date of Birth
 - Gender
 - Contact Information (Mobile Number)
 - Brief description of symptoms, Treatment
2. The patient can search available insurance plans.
 - Refer policy bazaar for more plans. <https://health.policybazaar.com/>
3. The patient selects a suitable insurance plan and updates their profile.
4. The patient can raise the request to generate invoice for claim.
5. On successful invoice generation patient can raise the request for claim.

2. Healthcare Service and Billing

1. The healthcare provider logs into the system.
2. The provider adds details of services rendered and generates an electronic invoice with following details.
 - Invoice Number: INV2023-001
 - Invoice Date: August 15, 2023
 - Due Date: September 15, 2023
 - Patient ID: PAT123456
 - Patient Name: John Doe
 - Patient Address: 123 Main Street, City, State, ZIP
 - Consultation Fee: 5675
 - Diagnostic Tests Fee: 2000
 - Diagnostic Scan Fee: 6000
 - Prescribed Medications Bill Amount: 13675
 - Tax (8%): for bill amount

- find total due amount = bill amount + tax.
 - Fill 0(zero) for fee if not applicable.
3. The patient accesses the invoice simply update status by paid.
 4. The healthcare provider submits the claim form from the patient.

3. Claim Submission and Processing

1. The patient submits a claim electronically from their dashboard, attaching relevant medical documents.
 - The patient fills out the necessary claim details, which may include:
 - Patient information (name, date of birth, address, insurance information).
 - Medical service details (diagnosis, treatment, date of service, claim amount, invoice amount by healthcare provider).
2. The insurance company reviews the claim.
3. They review incoming claims, verifying patient insurance plan coverage.
4. Claim can be rejected or approved, if approved the insurance company processes the claim and initiates payment.
5. Insurance company can view patient claim history with invoice amount, claim amount, date claim submission and date claim approved.

4. Administrator Dashboard

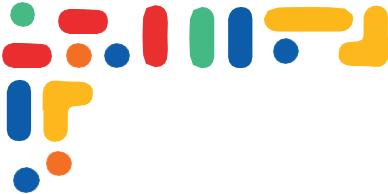

1. The administrator logs into the system and accesses the dashboard.
2. The dashboard displays user accounts, claims, payments.
 - history of all claim details (user name, claim amount, invoice amount, status of claim) should be displayed as table with above mentioned details.
3. The administrator manages user accounts.
 - registered user details should be displayed in table.
 - registered health care, insurance company details should be displayed in table.

5. Security and Compliance:

User authentication and authorization are enforced to ensure data privacy.

1. JWT Authentication:

JWT authentication involves generating a token upon successful user login and sending it to the client. The client includes this token in subsequent requests to authenticate the user.

4. User Login: Upon successful login (using valid credentials), generate a JWT token on the server.
5. Token Payload: The token typically contains user-related information (e.g., user ID, roles, expiration time).
6. Token Signing: Sign the token using a secret key known only to the server. This ensures that the token hasn't been tampered with.
7. Token Transmission: Send the signed token back to the client as a response to the login request.
8. Client Storage: Store the token securely on the client side (e.g., in browser storage or cookies).

2. JWT Authorization:

JWT authorization involves checking the token on protected routes to ensure that the user has the required permissions.

9. Protected Routes: Define routes that require authentication and authorization.

10. Token Verification:

- Extract the token from the request header.
- Verify the token's signature using the server's secret key.

11. Payload Verification:

- Decode the token and extract user information.
- Check user roles or permissions to determine access rights.

12. Access Control: Grant or deny access based on the user's roles and permissions.

Logout:

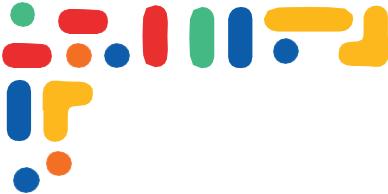

13. Logging out involves invalidating the JWT token on both the client and the server to prevent further unauthorized requests.

6. User Profile:

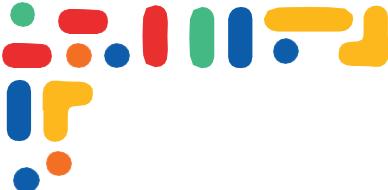

- Each actor of the application must have a user profile page.
- Profile page must allow the user to upload picture, edit/delete information such as name, phone number.
- It is recommended to have change password feature in profile page.

Project Development Guidelines

The project to be developed based on the below design considerations.

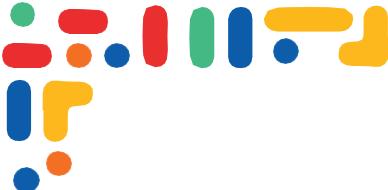

1	Backend Development	<ul style="list-style-type: none">• Use Rest APIs (Springboot/ASP.Net Core WebAPI to develop the services.• Use Java/C# latest features.• Use ORM with database.• perform backend data validation.• Use Swagger to invoke APIs.• Implement API Versioning.• Implement security to allow/disallow CRUD operations.• Message input/output format should be in JSON (Read the values from the property/input files, wherever applicable). Input/output format can be designed as per the discretion of the participant.• Any error message or exception should be logged and should be user-readable (not technical).• Database connections and web service URLs should be configurable.• Implement JWT for Security.• Follow Coding Standards with proper project structure.
2	Error Handling and Exception Management	<ul style="list-style-type: none">• Ensure errors and exceptions are handled with the status code.• Ensure that there are appropriate error-handling mechanisms in place to handle unexpected situations gracefully. Implement custom exceptions.• Ensure robust error logging and reporting mechanisms.
3	Testing and Debugging:	<ul style="list-style-type: none">• Implement Unit Test Project for testing the API.• Establish what each unit test aims to verify request mappings, status codes, returned views or response bodies.• Focus on business logic and typically mock away data access layers.• Ensure the interaction with the database behaves as expected.<ul style="list-style-type: none">• Test Structure• Arrange: Set up the test data and mocks.• Act: Execute the method being tested.• Assert: Verify the output or behavior with assertions.
4	Logging	<ul style="list-style-type: none">• Define different logging levels (e.g., DEBUG, INFO, WARN, ERROR) based on the severity of the logged message.• Ensure that log messages are descriptive and informative, providing enough context to understand the event or condition being logged.• Include relevant information such as timestamps, user IDs, and error codes in log messages.• Must be logged in a separate file under the source folder of the application.
5	Email notification	<ul style="list-style-type: none">• send email notification to the user when there is user action performed.

		<ul style="list-style-type: none">notify the user when user logged in into the profile and when database interaction is performed the notification are send to corresponding email.
6	File Management	<ul style="list-style-type: none">PDF formats should be used for bills/invoices and such kinds.Ensure to format the data properly in the PDF and make it downloadable and sharable via email.If the application (like quiz tool) has a way to interact with excel/csv (like bulk upload/download) implementation is a must.

Frontend Development Constraints

1.	Layout and Structure	Create a clean and organized layout for your registration and login pages. You can use a responsive grid system (e.g., Bootstrap or Flexbox) to ensure your design looks good on various screen sizes.
2	Visual Elements	Logo: Place your application's logo at the top of the page to establish brand identity.
		Form Fields: Include input fields for email/username and password for both registration and login. For registration, include additional fields like name and possibly a password confirmation field.
		Buttons: Design attractive and easily distinguishable buttons for "Register," "Login," and "Forgot Password" (if applicable).
		Error Messages: Provide clear error messages for incorrect login attempts or registration errors.
		Background Image: Consider using a relevant background image to add visual appeal.
		Hover Effects: Change the appearance of buttons and links when users hover over them.
3.	Color Scheme and Typography	Choose a color scheme that reflects your brand and creates a visually pleasing experience. Ensure good contrast between text and background colors for readability. Select a legible and consistent typography for headings and body text.
4.	Registration Page, Invoice Generation page, Claim submission page	Form Fields: Include fields for users to enter their name, email, password, and any other relevant information. Use placeholders and labels to guide users.
	Validation: Implement real-time validation for fields (e.g., check email format) and provide immediate feedback for any errors.	
	Form Validation: Implement client-side form validation to ensure required fields are filled out correctly before submission.	
	Registration Page	Password Strength: Provide real-time feedback on password strength using indicators or text. Password Requirements: Clearly indicate password requirements (e.g., minimum length, special characters) to help users create strong passwords.

		Registration Success: Upon successful registration, redirect users to the login page.
5.	Login Page	Form Fields: Provide fields for users to enter their email and password.
		Password Recovery: Include a "Forgot Password?" link that allows users to reset their password.
6.	Common to React/Angular	<ul style="list-style-type: none">• Use Angular/React to develop the UI.• Implement Forms, databinding, validations, error message in required pages.• Implement Routing and navigations.• Use JavaScript to enhance functionalities.• Implement External and Custom JavaScript files.• Implement Typescript for Functions, Operators.• Any error message or exception should be logged and should be user-readable (and not technical).• Follow coding standards.• Follow Standard project structure.• Design your pages to be responsive so they adapt well to different screen sizes, including mobile devices and tablets.

Good to have implementation features:

- Generate a SonarQube report and fix the required vulnerability.
- Use the Moq framework as applicable.
- Create a Docker image for the frontend and backend of the application.
- Implement OAuth Security.
- Implement design patterns.
- Deploy the docker image in AWS EC2 or Azure VM.
- Build the application using the AWS/Azure CI/CD pipeline. Trigger a CI/CD pipeline when code is checked-in to GIT. The check-in process should trigger unit tests with mocked dependencies.
- Use AWS RDS or Azure SQL DB to store the data.
